

Strategy-specific evidence retention creates a schedule-dependent recovery pattern
(not a verified withdrawal-residence effect; see Step 6 sensitivity)

(a) Recovery across scheduled exposure lengths under symmetric and asymmetric retention

(b) Stronger η_e asymmetry progressively lowers recovery
($\eta_w = 0.997$, cumul. retained ≈ 0.55 at $T=200$; n = 100)

(c) Fixed-schedule recovery threshold by exposure length under asymmetric retention (n = 80 per cell)
